Modular Lie algebras: new trends

A.I. Kostrikin, A.S. Dzhumadil’daev

Abstract. The article deals with next three problems. 1. What are ways for the origin of parameters in the structure tensor of finite-dimensional simple modular Lie algebra? A both "naive" approach, and a standard way through cohomology are discussed in this connection. 2. A determination of general deformations of modular Lie algebras suggest quite different problems and specific ways for their decision. 3. Presentation of maximal nilpotent subalgebras in Lie algebras of the Cartan type is compared with J.-P. Serre presentation in the classical case. A special attention is turned into Lie algebras over fields of small characteristic. Four tables summarise a lot of calculations.

1991 Mathematics Subject Classification: 17B05, 17B20, 17B50, 17B56.

1. Introduction. In our talk we shall discuss three topics: tensor products of Lie structures, deformations and defining relations. Common source of these topics is cohomology.

Our results are illustrated by the following observation. All cocycles (cycles) can be of the following three kind.

- Very large characteristic cocycles, i.e., cocycles that will remain cocycles for \( p \to \infty \); they can be considered as cocycles of characteristic 0; examples of these kind of cocycles are in the section 3.

- Large characteristic cocycles, i.e. cocycles that are defined for characteristic \( p \) beginning with some \( N \), say \( p > 11 \), but they will not be cocycles for \( p \to \infty \); examples of these kind are derivations of form \( D^p \) (1-cocycles), and \( SqD \) (2-cocycles).

- Small characteristic cocycles; they have no analogy for large characteristics; local deformation cocycle of nonrestricted Hamiltonian algebra in characteristic \( p = 5 \) gives us the example of small characteristic cocycles (the corresponding deformation is isomorphic to Melikyan algebra); another example can be get from the list of defining relations additional to Serre relations (Table 1) and from the list of 2-cocycles for Zassenhaus algebra, \( p = 2 \) (Table 2).
It is impossible to give exact border between characteristics. It depends from
the problem under consideration. It depends also from the concrete situation.
Moreover, very large characteristic case can be included into the case of large
characteristic. Very large characteristic case can be understood as a case of char-
acteristic 0.

Example 1. Serre defining relations for nilpotent subalgebra $\mathcal{L}_+$ of classical Lie
algebra are generated by positive root vectors. The border between large and
small characteristics is 5. There is no difference between large and very large
characteristics respectively for the problem on defining relations of $\mathcal{L}_+$. Exact
meaning of these statements is the following one: if $p > 3$ then defining relations
of $\mathcal{L}_+$ are just the same as in characteristic 0, i.e. $\mathcal{L}_+$ is generated by Serre
relations $(ad e_i)^{-1-a_{ij} e_j} = 0$; additional relations are appear in the cases of small
characteristics $p = 2, 3$. The list of additional relations is given in the Table 1.

Example 2. Classification problem of finite-dimensional simple Lie algebras over
an algebraically closed field of characteristic $p$: according Kostrikin-Shafarevich
conjecture the border between small and large characteristics pass through 7; ac-
cording Kac conjecture this border is 5. The modification of Kostrikin-Shafarevich
conjecture says that there is no border between small characteristics and large
characteristics cases. In right understanding of the notion of deformation almost
all new simple algebras appeared at the last time in small characteristics will be
deformations of Cartan Type Lie algebras. Note that dimensions of simple Lie
algebras in small characteristics, except Brown algebra, are not new. We think that
this fact is not occasional. We suggest that deformations should be considered in
the sense of Gerstenhaber. More general approach, outlined in [17, 23], especially
for Lie algebras over fields of small characteristic, will be out of discussion.

At first, we should like to explain, on an intuitive level, the origin of parametric
structure tensor. Parametric families of simple Lie algebras over algebraically
closed field are due to characteristic $p > 0$. Nevertheless, as we shall see soon, it
is not so easy to construct a family by direct approach.

The work was supported in part by the RFBR, Grant No. 98-01-00146 and the
INTAS, Grant No. 98-M048 (A.I. Kostrikin), and the INTAS, Grant No. 93-2618-
Ext (A.S.Dzhumadil’daev). The second author is deeply grateful to A.Caranti
and C.Löfwall for checking some calculations in computer.

2. Tensor product of Lie structures. Basic definitions. Let $A, B$ be two
commutative associative algebras over an algebraically closed field $k$ with the
common unit 1. Let $*[*,*]_A, [*,*]_B$ be Lie algebra structures on $A, B$ (by the Poisson
bracket or in another way). Let us define Lie algebra structure $(A \otimes B, [*,*])$ on
their tensor product in the following way:

$$[a \otimes b, a' \otimes b'] = \lambda a a' \otimes [b, b'] + \mu [a, a']_A \otimes b b'.
\tag{1}$$
Here is \( \lambda, \mu \in k, \lambda \mu \neq 0; \lambda \) and \( \mu \) do not depend on elements of algebras. Is it possible? When it is the case we shall speak on the tensor product of Lie structures:

\[
\mathcal{L} = \mathcal{L}(\lambda, \mu)
\]

Our aim is to give some useful examples both of positive and negative nature.

Anticommutativity of the product (1), linearly extendable on the all elements of \( A \otimes B \), is evident. The Jacobi identity may be the obstacle to the extendability of Lie structures on their tensor product. As \( \lambda, \mu \neq 0 \), we have

\[
[[f \otimes u, g \otimes v], h \otimes w] + [[h \otimes w, f \otimes u], g \otimes v] + [[g \otimes v, h \otimes w], f \otimes u] = 0
\]

(2) \( (f, g, h \in A, u, v, w \in B) \) precisely when

\[
[f, g, h] \otimes [u, v, w] + [f, g]h \otimes [u, w] + [h, f]g \otimes [u, v] + [gh, f] \otimes [v, w, u] = 0
\]

(3)

(the left part of the expression (3) enters with coefficient \( \lambda \mu \) in the left part of (2); coefficients \( \lambda^2, \mu^2 \) will be under null members, as a consequence of the Jacoby identity in algebras \( A, B \)).

The natural question arises: when the identity (3) is true and what properties of input structures are inherited? If we have no restrictions on \( A, B \), the problem will be too general. In our situation the case \( k > 0, \dim_k A < \infty, \dim_k B < \infty \) is the most suitable one. More precisely, we pay attention to Lie algebras of Cartan type, using notation and the main definitions from the survey paper [16]. So, \( A, B \) (in associative sense) will be algebras of divided powers.

3. Tensor product of Lie structures. Some calculations and results.

Example 3. \( W_1(m) = \langle x^{(i)}, m \rangle \). Divided powers \( x^{(i)} \), \( 0 \leq i \leq p - 1 \), \( p = \text{char } k \), are multiplied as usual: \( x^{(i)}x^{(j)} = (i+j)x^{(i+j)} \). A derivative \( f' \) of the element \( f \in W_1(m) \) is by definition \( (x^{(i)})' = x^{(i-1)} \). A commutation \( [f, g] = fg' - f'g \) set on \( W_1(m) \) the structure of simple Lie algebra, which is known as the Zassenhaus algebra (if \( p = 2 \), the ideal \( \langle x^{(i)} \mid i \leq 2^m - 2 \rangle \) is simple).

A direct verification shows that \( W_1(m) \otimes W_1(n) \) is a Lie algebra; the calculations connected with (3) are lengthy but straightforward. It is rather interesting to look at the structure of it. For the simplicity we restrict ourself to the case of the Witt algebra \( W_1 = W_1(1) \), when we can take

\[
A := W_1 = \langle 1, x, \ldots, x^{p-1} \mid x^p = 0 \rangle, \quad (x^k)' = kx^{k-1}.
\]

Let \( B := \langle y^i \mid 0 \leq i \leq p - 1 \rangle \) be another copy of \( W_1 \). Also, we put \( \mu = 1 \), so that

\[
L := W_1 \otimes W_1 = \langle x^i \otimes y^k \mid 0 \leq i, k \leq p - 1 \rangle,
\]

\[
[x^i \otimes y^k, x^j \otimes y^l] = (j - i)x^{i+j-1} \otimes y^{k+l} + \lambda(l - k)x^{i+j} \otimes y^{k+l-1}.
\]

(4)
Having in mind (4), we consider elements
\[ T_n = \sum_{k=0}^{n} (-1)^k \binom{n}{k} \lambda^k x^k \otimes y^{n-k}. \]
Specifically,
\[ T_0 = 1 \otimes 1, \quad T_1 = 1 \otimes y - \lambda x \otimes 1. \]
It is not so hard to see that
\[ L = \bigotimes_{n=0}^{p-1} L_{-n}, \quad L_{-n} = \langle T_n, xT_n, \ldots, x^{p-1}T_n \rangle, \]
What is more important, for any \( f, g \in A \) we have:
\[ [fT_m, gT_n] = \sum_{k,l} (-1)^{k+l} \binom{m}{k} \binom{n}{l} \lambda^{k+l} [fx^k \otimes y^{m-k}, gx^l \otimes y^{n-l}] \]
\[ = \cdots \text{(very tedious calculations)} = [f, g] \cdot T_{m+n}, \]
so that the preset parameter \( \lambda \in k \) disappeared. In fact,
\[ L_0 = W_1, \quad [L_0, L_n] = L_n, \quad [L_m, L_n] = L_{m+n}, \]
and \( L \) is a direct sum of adjoint \( W_1 \)-modules. Furthermore, \( \bigoplus_{n \geq 1} L_n \) is a nilpotent radical of \( L \).

**Example 4.** If \( f \) and \( g \) are functions of \( 2s \) variables \( x_1, x_{s+1}, \ldots, x_s, x_{2s} \), then the Poisson bracket
\[ \{ f, g \} = \sum_{i=1}^{s} (\partial_i f \partial_{s+i} g - \partial_{s+i} f \partial_i g), \]
introduced at first in analytical mechanics, equip the function space with the Hamiltonian Lie algebra structure. It is connected with the nondegenerate differential form
\[ \omega = \sum_{i=1}^{s} dx_i \wedge dx_{s+i}. \]
The geometric quantization on a corresponding symplectic manifold leads to a formal deformation of the Poisson bracket. After all this circumstance finds a reflection in the modular case.

Let us consider the simplest case of two variables:
\[ A = H_1(m, n; \omega) = \langle x^{(i)} y^{(j)} | 0 \leq i < p^m, 0 \leq j < p^n \rangle, \]
\[ B = H_1(q, r; \omega) = \langle z^{(k)} t^{(l)} | 0 \leq k < p^q, 0 \leq l < p^r \rangle. \]
Here $\omega = dx \wedge dy$ is for $A$, and $\omega = dz \wedge dt$ is for $B$, so that

$$[a, a']_A = \partial_x a \partial_y a' - \partial_y a \partial_x a', \quad [b, b']_B = \partial_x b \partial_y b' - \partial_y b \partial_x b'$$

(5)

(generally speaking, we should take in (5) opposite signs, but it is not so essential).

Thus, we have:

$$[\lambda(i, j) \otimes z(k)l(j), \lambda(i', j') \otimes z(k')l(l')] = \lambda(j + j' - 1, i + i' - 1, k + k' - 1)$$

(6)

$$\lambda(i, j) \otimes z(k)l(j), \lambda(i', j') \otimes z(k')l(l')$$

give simple Lie algebras, while

$$\lambda(0, 0) \otimes \lambda(0, 0) \otimes \lambda(0, 0), \lambda(0, 0) \otimes \lambda(0, 0) \otimes \lambda(0, 0), \lambda(0, 0) \otimes \lambda(0, 0) \otimes \lambda(0, 0)$$

Put $\bar{x} = x^{(p+m-1)}, \bar{y} = y^{(p+m-1)}, \ldots$. It is not so hard to see that $\bar{xy} \otimes \bar{zt} \notin [L(\lambda, \mu), L(\lambda, \mu)]$. Indeed, if we take, for example $p > 2$, $i + i' = p - m, j + j' = p$, $m + k + l = p$, then $k + k' + l + l' \equiv 0 \pmod{2}$, and (6) results in

$$\lambda(i + i' - 1, j + j' - 1, k + k' - 1) = \lambda(-1)^{j + j'} \lambda(k + k' - 1, l + l' - 1) \bar{xy} \otimes \bar{zt} = 0.$$

By putting

$$e(i, j, k, l) := \frac{1}{\mu^{i+j} \lambda^{k+l}} \lambda(i, j) \otimes z(k)l(l)$$

we get basis with multiplication, free of any parameters. If we shall throw out $\bar{xy} \otimes \bar{zt}$ and factorize upon the ideal, generated by $1 \otimes 1$, then we came to the Hamiltonian simple Lie algebra

$$L(\lambda, \mu) \cong L(1, 1) \cong H_2,$$

corresponding to the differential form $\omega(x, y, z, t) = dx \wedge dy + dz \wedge dt$.

It is well known that for $s = 1$ along with $\omega_0 := \omega = dx \wedge dy$ there exist more forms:

$$\omega_1 = (\exp y) \cdot dx \wedge dy; \quad \omega_2 = (1 - \bar{xy}) \cdot dx \wedge dy,$$

which are result in filtered (nongraded!!) deformations $(H_1, \omega_1), \ (H_1, \omega_2)$ of $(H_1, \omega_2)$.

By extending our direct checking we arrive to the conclusion that the tensor products

$$(H_1, \omega_0) \otimes (H_1, \omega_0), \ (H_1, \omega_0) \otimes (H_1, \omega_2), \ (H_1, \omega_2) \otimes (H_1, \omega_2)$$

give simple Lie algebras, while

$$(H_1, \omega_0) \otimes (H_1, \omega_1), \ (H_1, \omega_1) \otimes (H_1, \omega_2), \ (H_1, \omega_1) \otimes (H_1, \omega_1)$$
have not Lie algebra structure. Alike, tensor products
\[ H_1 \otimes W_1, \ H_1 \otimes K_1, \ K_1 \otimes K_1 \]
(where \( K_1 \) is the contact Lie algebra, corresponding to the form \( \omega = dz + ydx - xdy \)) do not lead to a Lie structure.

As a whole, the construction under consideration gives rather interesting examples of Lie algebras. In principle, a tensor product \( H_s \otimes H_t \) with \( s > 1 \) would give a parametric family.

4. Deformations. The following conjecture was proved by R.Block, H.Strade, R.L. Wilson [1, 24, 25].

**Conjecture 1.** Any finite-dimensional Lie algebra of simple Lie algebra over an algebraically closed field of characteristic \( p \geq 7 \) is isomorphic to either

- classical Lie algebra;
- Lie algebra of Cartan Type;
- deformations;

Here we would like to be more precise what deformations we mean. There are at least three kinds of deformations applicable respectively to simple Lie algebras. It is well known that Cartan type Lie algebras are defined by differential forms. By deformations one can understand deformation of corresponding differential forms. Deformations of differential forms are described in [15, 26, 21, 28]. We know that all Cartan Type Lie algebras have long filtration. One can understand deformations in the sense of filtered deformations. In [8] such deformations are called \( \{ L_i \} \)-deformations. Problem in this case means that for given graded algebra with homogeneous subspaces \( L_i \) one should find filtered algebra

\[ \mathcal{L} \supset \mathcal{L}_0 \supset \mathcal{L}_1 \supset \cdots \supset \mathcal{L}_r \]

such that \( \text{gr}\mathcal{L} \cong L \). Filtered deformations are described in [15]. The last kind of deformations — Gerstenhaber deformations [13] — are applicable to any algebra \( A \). Special properties of algebras like existence of filtration or differential forms are not necessary. Gerstenhaber deformations are ruled by two cohomology groups, \( H^2(A, A) \) and \( H^3(A, A) \). More exactly, if \( A \) is a Lie algebra with vector space \( V \) over a field \( F \) and commutator \( V \times V \rightarrow V, \ (a, b) \mapsto [a, b] \) then Gerstenhaber deformation of \( A \) is defined on the vector space \( V_t := V \otimes F((t)) \) by multiplication

\[ [a, b]_t = [a, b] + t f_1(a, b) + t^2 f_2(a, b) + \cdots, \]

where

\[ f_1, f_2, \ldots \in C^2(V, V). \]
Jacobi identities on the new commutator \([ , ]\), are reduced to a series of conditions

\[
\sum_{i=1}^{k} f_i * f_{k-i} = -d f_k, \quad k = 1, 2, \ldots
\]

where

\[
f * g(a, b, c) = f(g(a, b), c) + f(g(b, c), a) + f(g(c, a), b),
\]

\[
d h(a, b, c) = h([a, b], c) + h([b, c], a) + h([c, a], b)
\]

\[
+ [h(a, b), c] + [h(b, c), a] + [h(c, a), b],
\]

for \( f, g, h \in C^2(V, V) \). The first deformation term \( f_1 \) is called local deformation. From deformation equations it follows that any local deformation should be 2-cocycle of the adjoint module:

\( f_1 \in Z^2(A, A) \).

If we get any cocycle \( \psi \) instead of \( f_1 \) one can ask about constructing of prolongations \( f_2, f_3, \ldots \), that satisfy deformation equations. In other words in each step \( k \) one should check whether the following 3-cocycle

\[
\sum_{i=1}^{k} f_i * f_{k-i} \in Z^3(A, A)
\]

will be a coboundary

\[
\sum_{i=1}^{k} f_i * f_{k-i} = -d f_k \in B^3(A, A).
\]

If it is the case for any \( k \) then we say that the local deformation \( f_1 = \psi \) has prolongation to global deformation. In this sense, studying of Gerstenhaber deformations is reduced to the question on calculating second cohomology group \( H^2(A, A) \) and third cohomology group \( H^3(A, A) \). Experience shows that all filtered deformations and deformations of differential forms of Cartan Type Lie algebras can be realized as a Gerstenhaber deformations. We are not sure whether in general all Gerstenhaber deformations should be filtered deformations for some filtration.

Our modification of Kostrikin-Shafarevich conjecture is the following one. Deformations should be understand as a Gerstenhaber deformations. If this is the case, the number of new simple Lie algebras that appear in small characteristics will be restricted essentially. This modified conjecture is supported not only by the observation that dimensions of new simple Lie algebras in \( p = 2, 3 \) on the whole are known ones, i.e. dimensions of four series of Cartan Type Lie algebras. In some cases one can construct exact realisation of some new simple Lie algebras as a Gerstenhaber deformations. Let us give realisation of Melikyan algebra (recall that all simple Lie algebras in characteristic 5 except this algebra satisfy
Kostrikin-Shafarevich conjecture) as a deformation of Hamiltonian algebra. Another interpretation of Melikyan algebra is in the paper [18].

5. Deformations. Melikyan algebras as a deformation of Hamiltonian algebras. Let \( L = H_2(n_x, n_y) \) be the Hamiltonian algebra over a field \( F \) of characteristic \( p = 5 \) of dimension \( p^{n_x+n_y} \), i.e. as a vector space \( L \) coincides with a space of divided power algebra \( O_2(n_x, n_y) \) and multiplication is given by

\[
[u, v] = \partial_x(u)\partial_y(v) - \partial_y(u)\partial_x(v).
\]

(we changed here a sign on the opposite one). Consider cochains \( \psi_1, \psi_2 \in Z^2(L, L) \), such that

\[
\psi_1 = \partial_x^2 \land \partial_y^3, \quad \psi_2 = \Delta_1 \land \partial_x^5,
\]

where

\[
\Delta_1(u) = u - x\partial_x(u).
\]

Then for

\[
[\cdot, \cdot]_{\varepsilon_1, \varepsilon_2} = [\cdot, \cdot] + \varepsilon_1\psi_1 + \varepsilon_2\psi_2,
\]

we have

\[
\text{Jac}([\cdot, \cdot]_{\varepsilon_1, \varepsilon_2}) = (3\varepsilon_1^2 + \varepsilon_1\varepsilon_2)\partial_x^5 \land \partial_x^2 \land \partial_y^2.
\]

In particular, \( \psi_1, \psi_2 \in Z^2(L, L) \). The 3-cocycle \( \partial_x^2 \land \partial_y^3 \land \partial_x^5 \in C^3(L, L) \) is nontrivial: if

\[
\partial_x^2 \land \partial_y^3 \land \partial_x^5 = d\omega
\]

for some \( \omega \in C^2(L, L) \) then we will have

\[
1 = \partial_x^2 \land \partial_y^3 \land \partial_x^5(x^5, x^3, x^2) = [\omega(x^5, x^3), x^2] + [\omega(x^3, x^2), x^5] + [\omega(x^2, x^5), x^3],
\]

that is impossible because of \( 1 \notin \{L, L\} \). So, the local deformation \( \varepsilon_1\psi_1 + \varepsilon_2\psi_2 \) can be prolongated if and only if

\[
\varepsilon_1(3\varepsilon_1 + \varepsilon_2) = 0.
\]

We obtain Lie algebra defined on the space \( O_2(n_x, n_y), p = 5 \), by multiplication

\[
[\cdot, \cdot]_{\varepsilon} = \partial_x \land \partial_y + \varepsilon(\partial_x^2 \land \partial_y^3 + 2\partial_x^5 \land \partial_y^5 - 2x\partial_x \land \partial_y^5).
\]

Denote it by \( L(\varepsilon) \).

Notice that the cocycle \( \psi = \psi_1 + 2\psi_2 \) is nontrivial, if \( n_x > 1 \), and trivial, if \( n_x = 1 \). If \( n_x = 1 \), then

\[
\psi = d\omega,
\]

where

\[
\omega(u_y^k) = \partial_1(u) y^{k+1}, \quad u = u(x).
\]
If $n_x > 1$ then the condition $\psi = d\omega_1$ gives us that
$$2 = \psi(1, x^5) = d\omega_1(1, x^5) = [x^5], \omega_1(1).$$
Since $[x^5], L \in \mathcal{L}_3$, it is not possible. So, $[\psi] \neq 0$, if $n_x > 1$.

The $p^{n_x+n_y}$-dimensional vector space $O_2(n_x, n_y)$ under the multiplication
$$[u, v]_\epsilon = \partial_u(u)\partial_v(v) - \partial_v(u)\partial_u(v) + \epsilon(\partial^2_u(u)\partial^2_v(v) - \partial^2_v(v)\partial^2_u(u))$$
is the Lie algebra, which we denote by $L(\epsilon)$.

**Theorem 1.** Let $p = 5, n_x > 1, n_y > 0$. The algebra $L(\epsilon)$ gives us Gerstenhaber deformation of the Hamiltonian algebra $H_1(n_x, n_y)$ by local deformation $\psi_1 + 2\psi_2$. The Melikyan algebra $L(n_x - 1, n_y)[20]$ is isomorphic to the algebra obtained from $L(\epsilon)$ by specialisation $\epsilon = 1$.

Let us give a initial part of the grading in $L(\epsilon)$:
$$L(\epsilon)_{-2} = \langle x^{[0]} : = \epsilon^{-1}1 \rangle \simeq K(-2),$$
$$L(\epsilon)_{-1} = \langle x^{[0]} : = x, x^{[1]} : = -\epsilon^{-1}x^{(2)}, x^{[2]} : = \epsilon^{-2}x^{(3)}, x^{[3]} : = -\epsilon^{-3}(x^{(4)} - \epsilon y) \rangle \simeq \bar{U}(1),$$
$$L(\epsilon)_0 = \langle e_{[-1]} : = x^{(4)}, e_{[0]} : = -xy, e_{[1]} : = \epsilon^{-1}x^{(2)}y, e_{[2]} : = -\epsilon^{-2}x^{(3)}y, e_{[3]} : = \epsilon^{-3}(x^{(4)}y - \epsilon y^{(2)}) \rangle + \langle x^{[0]} : = x^{(5)}y + \epsilon xy \rangle \simeq \bar{U}(1) \oplus K,$$
$$L(\epsilon)_1 = \langle x^{[0]} : = -x^{(4)}y, x^{[1]} : = xy^{(2)}, x^{[2]} : = -\epsilon^{-1}x^{(2)}y^{(2)}, x^{[3]} : = \epsilon^{-2}x^{(3)}y^{(2)}, x^{[4]} : = -\epsilon^{-3}(x^{(4)}y^{(2)} - \epsilon y^{(3)}) \rangle$$
$$+ \langle x^{[0]} : = \epsilon^2x^{(6)}, x^{[1]} : = -\epsilon x^{(7)}, x^{[2]} : = x^{(8)}, x^{[3]} : = x^{(5)} + \epsilon xy^{(2)} \rangle \simeq U(3) \oplus \bar{U}(1).$$

Here $U(t)$ is $W_1$-module endowed on divided power algebra $U = O_1(1)$ by formula
$$(u\partial)_t(v) = u\partial(v) + t\partial(u)v.$$
and has a submodule of codimension 1:

\[ U(1) = \langle x^{|i|} : 0 \leq i \leq p - 2 \rangle. \]

Recall also, that \( U(-1) \) is isomorphic to the adjoint module, and we denote its basic vectors by \( e_{|j|} := x^{i+1} \partial \). We denote by \( K(t) \) 1-dimensional \( W_{1} \ominus \langle c \rangle \) module with basic vector 1, such that \( W_{1}1 = 0, (c)_{1}1 = t \cdot 1 \). Notice that \( L(c)_{0} \) is isomorphic to direct sum of Witt algebra \( W_{1} \) and 1-dimensional center \( \langle c \rangle \).

Similar realisations of some Skryabin, Kuznetsov and Ermolaev (see [16] and further references there) algebras as a Gerstenhaber deformations also can be done.

6. Defining relations and nonsplit extensions. Finite-dimensional simple Lie algebras are called classical and have a lot of applications in mathematics and physics. In nonclassical case, i.e. in case of infinite-dimensional Lie algebras over a field of characteristic 0 and finite-dimensional of characteristic \( p > 0 \) there appear new four classes of simple Lie algebras. These algebras are called Cartan Type Lie algebras, since they correspond to four classes of vector fields Lie algebras. Recall their definitions in characteristic 0. General type \( W_{n} \) can be defined as a Lie algebra of Laurent polynomials in \( n \) variables, other three types can be defined as a subalgebras of general type saving some differential forms: special type \( S_{n} \subseteq W_{n+1} \) save volume form \( dx_{1} \wedge \cdots \wedge dx_{n} \), Hamiltonian type \( H_{n} \subseteq W_{2n} \) save form \( \omega_{H} = \sum\limits_{i=1}^{n} dx_{i} \wedge dx_{n+1} \) and contact type \( K_{n+1} \subseteq W_{2n+1} \) save contact form \( dx_{2n+1} + \omega_{H} \). An essential part of Serre defining relations \( (\langle ad e_{i} \rangle^{n_{i}} e_{j} = 0, i \neq j) \) corresponds to defining relations of graded nilpotent subalgebras, i.e. to 2-homology groups of subalgebras generated by positive roots. Similar things are true for nonclassical Lie algebras. Main part of defining relations of Cartan Type Lie algebra \( L \) corresponds to second homology group of maximal graded nilpotent subalgebra \( L_{1} \). In classical case, these subalgebras are symmetric. They are not so ladege and cycles are uniquely defined by Cartan matrix. Cartan type Lie algebras have no good root systems, and maximal subalgebras are very large. We have calculated \( H_{2} := H_{2}(L_{1}, C) \) for all four Cartan series.

Let \( L_{1} = \oplus_{i \geq 1} L_{i} \) be graded nilpotent Lie algebra. Then the first homology group \( H_{1}(L_{1}, k) \equiv L_{1}/[L_{1}, L_{1}] \) can be interpreted as a space of generators of \( L_{1} \) and the second homology group \( H_{2}(L_{1}, k) \) is interpreted as a group of defining relations [10]. More exactly, if elements \( E_{1}, \ldots, E_{k} \) can not be presented as commutators and their factor-classes in \( L_{1}/[L_{1}, L_{1}] \) constitute basis, then \( E_{1}, \ldots, E_{k} \) are generators of \( L_{1} \). Any element of \( L_{1} \) is a linear combination of commutators of \( E_{1}, \ldots, E_{k} \). If \( H_{2}(L_{1}, k) \) is \( r \)-dimensional and classes of cycles \( \sum_{s} E_{i} \wedge f_{i}(s), s = 1, \ldots, r \) constitute a basis, where \( f_{i}(s) \) are elements of \( L_{1} \) presented as a linear combination of generators \( E_{1}, \ldots, E_{k} \), then \( r \) relations

\[ [E_{i}, f_{i}(s)] = 0, \quad s = 1, \ldots, r, \]

gives us defining relations of \( L_{1} \).

For finite-dimensional simple classical Lie algebras defining relations are known as Serre defining relations. These relations can be devided into three parts. Rela-
tions of nilpotent subalgebra $\mathcal{L}_-$, generated by elements of negative roots

$$(\text{ad} \ f_i)^{-1-a_{ij}} \ f_j = 0,$$

and relations of nilpotent subalgebra $\mathcal{L}_+$ generated by elements of positive roots

$$(\text{ad} \ e_i)^{-1-a_{ij}} \ e_j = 0,$$

and compatibility conditions

$$[e_i, f_j] = \delta_{ij} h_i,$$

$$[h_i, e_j] = a_{ij} e_j, [h_i, f_j] = -a_{ij} f_j.$$  

Here $A = (a_{ij})$ is Cartan matrix. In homological terms relations (7) correspond to cycles $f_i \land (\text{ad} \ f_j)^{-a_{ij}} f_j$ of the group $H_2(\mathcal{L}_-, k)$, and relations (8) correspond to cycles $e_i \land (\text{ad} \ e_j)^{-a_{ij}} e_j$ of the group $H_2(\mathcal{L}_+, k)$.

Similar constructions take place for nonclassical Lie algebras too. For example, let $L = \oplus_{i \geq -2} L_i$ be a simple Lie algebra one of Cartan Types $W_n(\mathfrak{m}), S_n(\mathfrak{m}), H_n(\mathfrak{m}), K_n(\mathfrak{m})$. It has grading

$$L = \mathcal{L}_- \oplus L_0 \oplus \mathcal{L}_+,$$

where

$$\mathcal{L}_- = \oplus_{i < 0} L_i, \quad \mathcal{L}_+ = \oplus_{i > 0} L_i,$$

and $L_0$ are classical simple Lie algebras $\mathfrak{sl}_n$ for $S_n(\mathfrak{m})$, $\mathfrak{sp}_n$ for $H_n(\mathfrak{m})$, and split central extensions $\mathfrak{gl}_n$ for $W_n(\mathfrak{m})$, $\mathfrak{sp}_n \oplus k$ for $K_n(\mathfrak{m})$.

In contrast to classical case these gradings are not symmetric. A subalgebra $\mathcal{L}_-$ is "small": namely, it is an abelian algebra of dimension $\sim n$, isomorphic to $L_{-1}$ for $L \neq K_n(\mathfrak{m})$, and Heisenberg algebra $L_{-2} \oplus L_{-1}$ for $L = K_n(\mathfrak{m})$. On the contrary, a positive part is "large": $\mathcal{L}_+$ (we will denote it $\mathcal{L}_1$) is nilpotent algebra of dimension $\sim p^n$.

Calculations of homology groups of $\mathcal{L}_-$ are easy. For any Cartan types with the exception of contact, $\mathcal{L}_- = L_{-1}$, and

$$H_2(\mathcal{L}_-, k) \cong \wedge^2 L_{-1}.$$  

For contact type $\mathcal{L}_- = L_{-2} \oplus L_{-1}$, and

$$H_2(\mathcal{L}_-, k) \cong \wedge^2 L_{-1}/k.$$  

The calculation of $H_2(\mathcal{L}_+, k)$ is interesting also from the other point of view. According the Levi-Mal’cev theorem, any solvable extension of semisimple finite-dimensional algebra is split. In the case of positive characteristic it is not the case. Any modular Lie algebra has at least one nonsplit extension and the number of nonequivalent nonsplit extensions by irreducible modules is finite [6]. The question on describing nonsplit extensions of Cartan Type Lie algebras by irreducible modules can be reduced to the question on calculating second (co)homology groups $H_2(\mathcal{L}_+, k)$. So, roughly speaking problems on description of defining relations and nonsplit extensions for Cartan Type Lie algebras are equivalent.
In our talk we give examples of defining relations descriptions for nilpotent subalgebras in cases of small charactersitics (classical Lie algebras), large characteristics (Zassenhaus algebra) and very large characteristic (Cartan Type Lie algebras).

From these examples we can see that for nonclassical Lie algebras in general $H_2(L_+, k)$ is very big. Their dimensions are about constant multiple of $n^k$. But as a modules over 0-components $L_0$, they have a quite transparent structure.

7. Defining relations and nonsplit extensions. Defining relations for Classical Lie algebras. Let $a = (a_{i,j})$ be a Cartan matrix of rank $n$. By classical simple Lie algebras we understand simple Lie algebras over an algebraically closed field of characteristic $p > 0$ of the following types: $A_n(n > 1), B_n(n > 1, p > 2), C_n(n > 2, p > 2), D_n(n > 3), G_2(p > 3), F_4(p > 2), E_6, E_7, E_8$.

Recall that for small characteristics isomorphisms between different types are possible. For example, $G_2$ in the cases $p = 2, 3$ have ideals such that corresponding simple factors are isomorphic to algebras of types $A_2$ and $A_3$. Algebras $A_{np-1}$ have 1-dimensional centers with simple factors. Algebras $D_{2k+1}$, $E_7(p = 2)$ and $E_8(p = 3$ have also 1-dimensional ideals with simple factors. For $p = 2$ algebras of types $C_n$ have ideal $D_n$ and $F_4$ has ideal $D_4$.

The following result for the case of large and very large characteristic $p > 3$ follows from results of J.-P. Serre, G. Seligman, R.V. Moody, S. Berman. In the case of small characteristics it was obtained by A.S. Dzhumadil’daev and S. Ibraev.

**Theorem 2.** Let $L$ be a simple classical Lie algebra, $p > 0$, and $L_+$ be its nilpotent subalgebra generated by positive root vectors. If $p > 3$, then $L_+$ can be defined by Serre relations $(ad e_j)^{1+a_{i,j}}e_j = 0$, as in the case of zero characteristic. If $p = 2, 3$, then defining relations of $L_+$ consist of Serre defining relations and additional relations. The list of additional relations is given in the Table 1.

8. Defining relations and nonsplit extensions. Defining relations of $L_+$ for Zassenhaus algebra. Recall that Zassenhaus algebra $L = W_1(m)$ is $p^m$-dimensional and graded

$$L = \bigoplus_{i=1}^{p^m-2} L_i, \quad [L_i, L_j] \subseteq L_{i+j},$$

with 1-dimensional homogeneous components $L_i =< e_i >$. The multiplication on the basis $\{e_i : -1 \leq i \leq p^m - 2\}$ can be given by

$$[e_i, e_j] = N_{i,j} e_{i+j},$$

where

$$N_{i,j} = \binom{i+j+1}{j} - \binom{i+j+1}{i},$$

Let

$$L_{-1} \supset L_0 \supset L_1 \supset \cdots \supset L_{p^m-2} \supset 0,$$
\[ \mathcal{L}_i = \oplus_{j \geq 1} L_j, \]

be the standard filtration. Then

\[ \mathcal{L}_1/\mathcal{L}_1 \cong L_{-1} \oplus L_{-2} \oplus L_{p^k-1}. \]

In other words the first homology group \( H_1(\mathcal{L}_1, k) \) is \((m + 1)\)-dimensional and has a basis \( e_1, e_2, e_{p-1}, \ldots, e_{p^{m-1}-1} \). In particular, this means that any element \( e_i \) for \( i \neq 1, 2, p^k - 1 \) can be presented as a linear combination of above mentioned elements or their commutators. Fix for any \( e_i \) some of such presentation. Change all elements \( e_i \) in formal way by \( E_i \).

**Theorem 3.** For \( p > 7 \), the nilpotent subalgebra \( \mathcal{L}_+ \) of the Zassenhaus algebra \( W_1(m) \) is \((m + 1)\)-generated. It is generated by the elements \( E_1, E_2, E_{p^k-1} \), where \( 0 < k < m \), and the following defining relations:

\[
\begin{align*}
5[E_1, E_2] - 9[E_2, E_3] &= 0, \\
[E_2, E_5] - 2[E_3, E_4] &= 0, \\
(\delta_{i,k} + \delta_{s,k} - 1)[E_{p^k-2}, E_{p^l+p^r}] - 2[E_{p^k-1}, E_{p^l+p^r-1}] &= 0, 0 < k \leq l \leq s < m, \\
2[E_{p^k-1}, E_{p^l-1}] - [E_1, E_{p^l+p^r-1}] &= 0, 0 < k < l < m, \\
[E_1, E_{p^k-2}] &= 0, \\
[E_{p^k-1}, E_{p^l+p^r-1}] &= 0, k > 1, \\
[E_2, E_{p^m-2}] &= 0, \\
[E_1, E_{p^k}] + [E_2, E_{p^l-1}] &= 0, \\
(1 + \delta_{i,j})[E_2, E_{p^l+p^r-1}] + [E_{p^k-1}, E_{p^l+2}] &= 0, 0 < k \leq l < m, \\
[E_2, E_{p^k}] - 2[E_3, E_{p^l-1}] &= 0, \\
3[E_2, E_{p^l+1}] + 2[E_3, E_{p^k}] &= 0.
\end{align*}
\]

Here \( \delta_{i,j} = \delta(i = j) \) is the Kronecker symbol and elements \( E_i \) for \( i \neq 1, 2, p^k - 1 \) are defined as a linear combination of commutators of elements \( E_1, E_2, E_{p^k-1}, 1 < k < m \) just like in Zassenhaus algebra. For example,

\[
\begin{align*}
E_4 &:= [E_1, E_2]/2, \quad E_4 := [E_1, E_3]/5, \quad E_5 := [E_1, E_4]/9, \\
E_6 &:= [E_1, E_5]/14, \quad E_{p^k} := -[E_1, E_{p^k-1}].
\end{align*}
\]
Under above mentioned relations, definitions of $E_i$ do not depend of the choise of such presentations.

For $p = 0$ this result follows from results of Gelfand-Fuks [12]. For $p = 0$ it was proved also by Fialovski [11] and Ufnarovski [27]. For $p > 7$ this result in cohomological terms is given in [4].

What about small characteristics? For $p = 3, 4, 5, 7$ the above table will be changed not so much, but in the case of $p = 2$ the picture is quite different (see Table 2). Notice that in case of $p = 2$ weights are presented as a sum of powers of 2 and such presentations are not unique. Therefore repetitions of some cocycles in some weights are possible.

9. Defining relations and nonsplit extensions. Defining relations of $\mathcal{L}_+$ for nonclassical Lie algebras (the case of very large characteristic). As it was mentioned earlier, one of differences between simple Lie algebras of classical and nonclassical types is the following one. Nilpotent subalgebras of classical Lie algebras are symmetric and not so big. In nonclassical case these subalgebras are very big and in general not symmetric. Since $\mathcal{L}_-$ is abelian or isomorphic to Heisenberg algebra and calculations of homology groups for such algebras are very easy, we shall exclude the case $\mathcal{L}_-$ from the consideration.

As we mentioned above a modular result in the case of very large characteristic is a part of characteristic 0 results. That is why appearance of characteristic 0 result in our talk will not be surprising. What kind of characteristic $p$ cocycles can appear in addition to cocycles, obtained from characteristic 0, one can see, for example, in [9].

In this section we give description of defining relations of nilpotent subalgebra $\mathcal{L}_+$ for Cartan Type Lie algebra $L = W_n, S_n (n > 2), H_n, K_{n+1}$ in characteristic 0. Since $H_2(\mathcal{L}_+, k) \cong H^2(\mathcal{L}_+, k)$, this result in cohomological terms follows from results of [7]. Below we give descriptions of $H_2(\mathcal{L}_+, k)$ made by A.S. Dzhumadil’daev and R. Kerimbaev. Independently second homology group was calculated by D.Leites and E.Poletaeva [19]. In some particular cases they also were obtained in [14, 10]. As was mentioned above the group $H_2(\mathcal{L}_+, k)$ can be interpreted as a group of defining relations of $\mathcal{L}_1$. We give exact constructions for basic cycles and give an algorithm how to construct defining relations using cycles.

For classical simple Lie algebra $L_0$ of rank $n$ denote by $\pi_1, \ldots, \pi_n$ its fundamental weights and by $R(\pi)$ the irreducible module with weight $\pi$. Recall that $L_0 \cong sl_{n+1}$ for $L = S_n$ and $L_0 \cong sp_n$ for $L = H_n$. For $L = W_n$ when $L_0 \cong gl_n$, denote by $R(\pi, \lambda)$ the irreducible $gl_n$-module with weight $\pi$ (over $sl_n$) and conformal weight $\lambda$:

$$(x, \partial_j)_{\lambda} m = (x, \partial_j)m + (1 - \lambda)\delta(i = j)m, \ m \in R(\pi, \lambda), \lambda \in \mathbb{C}.$$ 

Similar definition for $L = K_{n+1}, L_0 \cong sp_n \oplus \mathbb{C}$, means that

$$(u)_{\lambda} m = (u)m + (\lambda - 2)\partial_0(u)m, \ u \in L_0, \ m \in R(\pi, \lambda), \lambda \in \mathbb{C}.$$
Below $\delta = 0$, if $n = 3$, and $\delta = 1$, if $n > 3$ and $\mathcal{L}_+ = \mathcal{L}_1$, $H_2(\mathcal{L}_1) = H_2(\mathcal{L}_1, \mathbb{C})$.

**Theorem 4.** Let $L = W_n$. If $n > 2$, then

$$H_2(\mathcal{L}_1) \cong H_2(\mathcal{L}_1)^{(2)},$$

and as $gl_n$ -module,

$$H_2(\mathcal{L}_1)^{(2)} \cong \delta R(2\pi_2 + \pi_{n-2}, 2) \oplus R(4\pi_1 + \pi_{n-2}, 2) \oplus R(2\pi_1 + \pi_2 + 2\pi_{n-1}, 3)$$

$$\oplus R(3\pi_1 + \pi_{n-1}, 2) \oplus R(\pi_1 + \pi_2 + \pi_{n-1}, 2)$$

$$\oplus R(\pi_1 + \pi_2 + \pi_{n-1}, 2) \oplus R(\pi_2, 1) \oplus R(\pi_1, 1).$$

If $n = 2$, then

$$H_2(\mathcal{L}_1) \cong H_2(\mathcal{L}_1)^{(2)} \oplus H_2(\mathcal{L}_1)^{(3)},$$

and as $gl_2$ -module,

$$H_2(\mathcal{L}_1)^{(2)} \cong R(3\pi_1 + \pi_{n-1}, 2) \oplus R(\pi_2, 1) \oplus R(\pi_2, 1),$$

$$H_2(\mathcal{L}_1)^{(3)} \cong R(7\pi_1, 3) \oplus R(5\pi_1, 2) \oplus R(\pi_1, 0).$$

If $n = 1$, then

$$H_2(\mathcal{L}_1) \cong H_2(\mathcal{L}_1)^{(7)} \oplus H_2(\mathcal{L}_1)^{(5)}.$$ 

**Corollary 1.** For $L = W_n$,

$$\dim H_2(\mathcal{L}_\infty) = n^2(n + 1)(3n^3 + 3n^2 - 4n - 14)/24 \sim n^6/8, \text{ if } n > 2,$$

$$= 25, \text{ if } n = 2,$$

$$= 2, \text{ if } n = 1.$$ 

**Theorem 5.** Let $L = S_n, n > 2$. Then

$$H_2(\mathcal{L}_1) \cong H_2(\mathcal{L}_1)^{(2)},$$

and as $sl_n$ -module,

$$H_2(\mathcal{L}_1)^{(2)} \cong \delta R(2\pi_2 + \pi_{n-2}) \oplus R(4\pi_1 + \pi_{n-2})$$

$$\oplus R(2\pi_1 + \pi_2 + 2\pi_{n-1}) \oplus R(\pi_1 + \pi_2 + \pi_{n-1}) \oplus R(\pi_2).$$

**Corollary 2.** For $L = S_n, n > 2$,

$$\dim H_2(\mathcal{L}_1) = (n + 1)n(n - 1)(3n^3 + 6n^2 - 10n - 24)/24 \sim n^6/8.$$
Theorem 6. Let $L = H_n$. If $n > 1$, then

$$H_2(L_1) \cong H_2^{(2)}(L_1) \oplus H_2^{(3)}(L_1),$$

and as $sp_n$-module,

$$H_2^{(2)}(L_1) \cong R(4\pi_1 + \pi_2) \oplus R(3\pi_2) \oplus R(2\pi_2) \oplus R(\pi_2) \oplus R(0),$$

$$H_2^{(3)}(L_1) \cong R(\pi_1).$$

If $n = 1$, then

$$H_2(L_1) \cong H_2^{(2)}(L_1) \oplus H_2^{(3)}(L_1) \oplus H_2^{(4)}(L_1),$$

and as $sl_2$-module,

$$H_2^{(2)}(L_1) \cong R(0),$$

$$H_2^{(3)}(L_1) \cong R(7\pi_1) \oplus R(\pi_1),$$

$$H_2^{(4)}(L_1) \cong R(2\pi_1).$$

Corollary 3. For $L = H_n$,

$$\dim H_2(L_1) = (2n - 1)n(8n^4 + 28n^3 + 34n^2 + 5n - 21)/18$$

$$\sim 8n^6/9, \text{ if } n > 1,$$

$$= 14, \text{ if } n = 1.$$

Theorem 7. Let $L = K_{n+1}$. If $n > 1$, then

$$H_2(L_1) \cong H_2^{(2)}(L_1),$$

and as $sp_n \oplus \mathbb{C}$-module,

$$H_2^{(2)}(L_1) \cong R(4\pi_1 + \pi_2, 0) \oplus R(3\pi_2, -6) \oplus R(2\pi_2, -4) \oplus R(\pi_2, -2) \oplus$$

$$R(0, -2) \oplus R(2\pi_1 + \pi_2, -2) \oplus R(4\pi_1, 2),$$

If $n = 1$, then

$$H_2(L_1) \cong H_2^{(2)}(L_1) \oplus H_2^{(3)}(L_1),$$

and as $sl_2 \oplus \mathbb{C}$-module,

$$H_2^{(2)}(L_1) \cong R(4\pi_1, 2) \oplus R(0, -2),$$
\[ H_2^{(3)}(\mathcal{L}_1) \cong R(7\pi_1, 0) \oplus R(5\pi_1, 2) \oplus R(3\pi_1, 0) \oplus R(\pi_1, -2) \oplus R(\pi_1, -2), \]

**Corollary 4.** For \( L = K_{n+1} \),

\[
\dim H_2(\mathcal{L}_1) = (2n + 1)(8n^5 + 20n^4 + 34n^3 + 7n^2 - 15n - 18)/18
\sim 8n^5/9, \text{ if } n > 1, \\
= 28, \text{ if } n = 1.
\]

Let us give an algorithm to write defining relations of \( \mathcal{L}_1 \) for Cartan Type Lie algebra \( L \). For simplicity we exclude the case \( L = W_1 \) from the consideration.

i) Take as generators of \( \mathcal{L}_1 \) elements \( e \) that corresponds to basic vectors \( e \) of \( L_1 \). Any element of \( L_k \) can be represented as a linear combination of commutators of \( L_1 \). Write, instead of elements of \( L_k \) that appear below, their expressions by \( L_1 \).

ii) Defining relations correspond to irreducible components of the decomposition of the \( L_0 \) -module \( H_2(\mathcal{L}_1) \). Let \( R(\pi) \) or \( R(\pi, \lambda) \) be one of such components. Take its highest vector and generate all other elements of the considered module. These elements should be in \( \wedge^2 \mathcal{L}_1 \).

iii) Change all exterior products \( \wedge \) in these elements by commutators \([\ , \ ]\), change all basic elements \( e \) by \( e \) and put obtained expressions equal to 0. These are defining relations of \( \mathcal{L}_1 \).

**Example.** \( L = H_1 \). Its nilpotent subalgebra \( \mathcal{L}_1 \) generates by 4 elements \( x^3, x^2 y, xy^2, y^3 \) and 14 defining relations: (below we use the notation \([a, b, c, d] := [a, [b, [c, d]]]\))

\[
[x^3, y^3] - 3[xy^2, x^2 y] = 0;
\]

\[
[x^3, [x^3, x^2 y]] = 0,
\]

\[
[x^3, [x^3, xy^2]] + 2[x^2 y, [x^3, x^2 y]] = 0,
\]

\[
3[xy^2, [x^3, x^2 y]] + 6[x^2 y, [x^3, xy^2]] + 2[x^3, [x^3, y^3]] = 0,
\]

\[
[y^3, [x^3, x^2 y]] + 6[xy^2, [x^3, xy^2]] + 6[x^2 y, [x^3, y^3]] + 2[x^3, [x^2 y, y^3]] = 0,
\]

\[
2[y^3, [x^3, xy^2]] + 6[xy^2, [x^3, y^3]] + 6[x^2 y, [x^2 y, y^3]] + [x^3, [xy^2, y^3]] = 0,
\]

\[
2[y^3, [x^3, y^3]] + 6[xy^2, [x^2 y, y^3]] + 3[x^2 y, [xy^2, y^3]] = 0,
\]
\[ 2[y^3, [x^2y, y^3]] + 3[xy^2, [xy^2, y^3]] = 0, \]
\[ [y^3, [y^3, xy^2]] = 0; \]
\[ [y^3, [x^3, y^3]] - 2[x^2y, [x^3, y^3]] + 3[xy^2, [x^3, xy^2]] - 2[y^3, [x^3, x^2y]] = 0, \]
\[ -2[x^3, [xy^2, y^3]] + 3[x^2y, [x^2y, y^3]] - 2[xy^2, [x^3, y^3]] + [y^3, [x^3, xy^2]] = 0; \]
\[ [x^3, x^3, xy^2, y^3] - 2[x^2y, x^3, x^2y, y^3] \]
\[ + 2[xy^2, x^3, x^3, y^3] - 2[y^3, x^3, x^3, xy^2] = 0, \]
\[ 9[x^3, x^2y, xy^2, y^3] - 18[x^2y, x^3, xy^2, y^3] \]
\[ + 12[xy^2, x^3, x^2y, y^3] - 4[y^3, x^3, x^3, y^3] = 0, \]
\[ 2[x^3, y^3, y^3, x^2y^2] - 2[x^2y, y^3, y^3, x^3] \]
\[ - 2[xy^2, y^3, x^3, xy^2] - [y^3, y^3, x^3, x^2y] = 0. \]

As examples, in the tables 3 and 4 we give constructions of heighest weight vectors for irreducible components of \( L_0 \)-modules of \( H_2(L_1, k) \) for \( L = H_n \) and \( L = K_{n+1} \).
